
Dear Author,

Please correct your galley proofs carefully and return them no more than four days after the page proofs have been received.

Please limit corrections to errors already in the text; cost incurred for any further changes or additions will be charged to the author, unless such changes have been agreed upon by the editor.

The editors reserve the right to publish your article without your corrections if the proofs do not arrive in time.

Note that the author is liable for damages arising from incorrect statements, including misprints.

Please note any queries that require your attention. These are indicated with a Q in the PDF and a question at the end of the document.

Reprints may be ordered by filling out the accompanying form.

Return the reprint order form by fax or by e-mail with the corrected proofs, to Wiley-VCH : afm@wiley.com

Corrections should be made directly in the PDF file using the PDF annotation tools. If you have questions about this, please contact the editorial office. The corrected PDF and any accompanying files should be uploaded to the journal's Editorial Manager site.

To avoid commonly occurring errors, **please ensure that the following important items are correct** in your proofs (please note that once your article is published online, no further corrections can be made):

- **Names** of all authors present and spelled correctly
- **Titles** of authors correct (Prof. or Dr. only: please note, Prof. Dr. is not used in the journals)
- **Addresses** and **postcodes** correct
- **E-mail address** of corresponding author correct (current email address)
- **Funding bodies** included and grant numbers accurate
- **Title** of article OK
- All **figures** included
- **Equations** correct (symbols and sub/superscripts)

Dear Author,

During the copyediting of your manuscript the following queries arose.

Please refer to the query reference callout numbers in the page proofs and respond to each by marking the necessary comments using the PDF annotation tools.

Please remember illegible or unclear comments and corrections may delay publication.

Many thanks for your assistance.

Query No.	Description	Remarks
Q-OO	<p>Open access publication of this work is possible via Wiley OnlineOpen. Information about this is available at: https://authorservices.wiley.com/author-resources/Journal-Authors/licensing-open-access/open-access/onlineopen.html.</p> <p>The cost of publishing your manuscript OnlineOpen may be covered by one of Wiley's national agreements. **Injectable Drug-Releasing Microporous
Annealed Particle Scaffolds for Treating
Myocardial Infarction**

A novel multimodal drug-releasing granular microstructured hydrogel (drugMAP) system, created by the microfluidic device, could decouple mechanical support and rapid tissue ingrowth, and also endow various pharmacological functions. The drugMAP loaded with drugs of forskolin and Repsox could significantly enhance left ventricular functions after local injection into infarcted hearts.

UNCORRECTED PROOF

Injectable Drug-Releasing Microporous Annealed Particle Scaffolds for Treating Myocardial Infarction

Jun Fang, Jaekyung Koh, Qizhi Fang, Huiliang Qiu, Maani M. Archang, Mohammad Mahdi Hasani-Sadrabadi, Hiromi Miwa, Xintong Zhong, Richard Sievers, Dong-Wei Gao, Randall Lee,* Dino Di Carlo,* and Song Li*

Intramyocardial injection of hydrogels offers great potential for treating myocardial infarction (MI) in a minimally invasive manner. However, traditional bulk hydrogels generally lack microporous structures to support rapid tissue ingrowth and biochemical signals to prevent fibrotic remodeling toward heart failure. To address such challenges, a novel drug-releasing microporous annealed particle (drugMAP) system is developed by encapsulating hydrophobic drug-loaded nanoparticles into microgel building blocks via microfluidic manufacturing. By modulating nanoparticle hydrophilicity and pregel solution viscosity, drugMAP building blocks are generated with consistent and homogeneous encapsulation of nanoparticles. In addition, the complementary effects of forskolin (F) and Repsox (R) on the functional modulations of cardiomyocytes, fibroblasts, and endothelial cells *in vitro* are demonstrated. After that, both hydrophobic drugs (F and R) are loaded into drugMAP to generate FR/drugMAP for MI therapy in a rat model. The intramyocardial injection of MAP gel improves left ventricular functions, which are further enhanced by FR/drugMAP treatment with increased angiogenesis and reduced fibrosis and inflammatory response. This drugMAP platform represents a new generation of microgel particles for MI therapy and will have broad applications in regenerative medicine and disease therapy.

1. Introduction

Ischemic heart disease (IHD) is a leading cause of global mortality, accounting for over nine million deaths per year, according to the World Health Organization (WHO).^[1] Acute MI is the most common manifestation of IHD, usually caused by the complete occlusion of a coronary artery with atherosclerotic plaque rupture and thrombosis.^[2] Following MI, the damaged myocardium eventually undergoes a remodeling process with cardiomyocyte depletion, tissue fibrosis, cardiac dilatation, and dysfunction, culminating in heart failure.^[3] Currently, several therapeutic strategies have been exploited to repair and regenerate the damaged cardiac tissues caused by MI, including pharmaceutical approaches,^[4] injectable hydrogels,^[5] cardiac patches,^[6] cell transplantation,^[7] and cell reprogramming.^[8] Among them, injectable hydrogels have shown great potential to

DOI: 10.1002/adfm.202004307

1 treat MI by providing mechanical support and tissue integra- 1
2 tion to increase myocardial thickness and prevent ventricular 2
3 remodeling through a minimally invasive and cost-effective 3
4 manner.^[5,9] Nevertheless, traditional hydrogels usually have a 4
5 trade-off between mechanical strength to support cell attach- 5
6 ment and porous structure to enable rapid tissue ingrowth 6
7 before hydrogel degradation. Thus, biomaterials with indepen- 7
8 dently tunable biophysical properties are needed to improve 8
9 therapeutic outcomes.^[5a] 9

10 Mechanical properties, porosity and microarchitecture of 10
11 porous hydrogels can significantly impact in vivo cell behavior 11
12 and tissue regeneration effects.^[10] Currently, a variety of man- 12
13 ufacturing techniques have been developed to fabricate struc- 13
14 tured porous hydrogel scaffolds, including solvent/porogen 14
15 leaching,^[11] gas foaming,^[12] freeze-drying,^[13] and 3D printing,^[14] 15
16 but these methods are challenging to be delivered via mini- 16
17 mally invasive techniques. To decouple porous structure and 17
18 mechanical support, we have recently developed an injectable 18
19 microporous annealed particle (MAP) scaffold by crosslinking 19
20 uniform microgel (μ Gel) building blocks produced in a micro- 20
21 fluidic device.^[15] By combining injectability, microporosity 21
22 and mechanical strength, the porous MAP scaffolds have 22
23 demonstrated rapid cellular infiltration without bulk material 23
24 degradation to facilitate wound and stroke healing in vivo.^[15a,16] 24
25 However, the therapeutic efficacy of MAP gel for treating MI 25
26 and its capabilities as a drug delivery platform to promote func- 26
27 tional regeneration remain to be investigated. 27

28 Pharmacological treatments are commonly used in clinic 28
29 to slow down or reverse detrimental cardiac remodeling in MI 29
30 patients,^[17] with specific effects such as proangiogenesis,^[18] 30
31 anti-fibrosis,^[18,19] anti-inflammatory,^[20] anti-cardiomyocyte 31
32 death,^[4b] antiarrhythmic,^[21] and anti-thrombosis.^[22] The cyclic 32
33 adenosine monophosphate (cAMP) is an essential second mes- 33
34 senger and mediates many critical intracellular signaling under 34
35 physiological and pathophysiological conditions.^[23] Activation 35
36 and increased generation of cAMP can markedly increase car- 36
37 diac LV function and survival, and attenuate cardiac fibrosis 37
38 and its sequelae after acute MI.^[24] Additionally, transforming 38
39 growth factor- β (TGF- β) signaling plays a pleiotropic role in 39
40 driving disease progression.^[25] TGF- β expression is upregu- 40
41 lated in acute MI and cardiac hypertrophy, which leads to 41
42 fibrosis and diastolic dysfunction with induced myodifferentia- 42
43 tion, extracellular matrix (ECM) synthesis, and cardiomyocyte 43
44 hypertrophy.^[26] Here we explored the approach to promote car- 44
45 diac regeneration by activating cAMP pathway while inhibiting 45
46 TGF- β signaling. Forskolin (F) is a cAMP agonist, and RepSox 46
47 (R) is a selective TGF- β inhibitor. Both small molecules have 47
48 shown the beneficial effects to rescue cardiac dysfunction and 48
49 ameliorate post-MI remodeling.^[27,38] However, it is unclear 49
50 whether there is a synergistic effect by modulating both sign- 50
51 aling pathways for heart repair. Furthermore, the majority of 51
52 drugs are administrated to patients by simple systemic delivery, 52
53 which generally leads to adverse off-target effects, drug toxicity, 53
54 and low treatment efficacy.^[28] In addition, a holistic approach is 54
55 still required to regenerate damaged human heart by targeting 55
56 multiple tissue pathologies, including remuscularization, elec- 56
57 tromechanical stability, angiogenesis, resolution of fibrosis, 57
58 and immunological balance.^[29] Therefore, biomaterial-based 58
59 scaffolds with localized multidrug delivery may be necessary to 59

1 promote cardiac regeneration by providing pleiotropic pharma- 1
2 ceutic effects. 2

3 In this study, we developed a novel injectable, multimodal 3
4 drugMAP hydrogel for MI therapy. The generation of a porous 4
5 drugMAP scaffold is shown schematically in **Figure 1**. Hydro- 5
6 phobic drugs were loaded into nanoparticles (NPs), which 6
7 were further encapsulated into matrix metalloprotease (MMP) 7
8 sensitive polyethylene glycol (PEG)-based μ Gel beads to gener- 8
9 ate drugMAP building blocks, i.e., drug/NPs- μ Gel beads, 9
10 using a flow-focusing microfluidic device. When the drugMAP 10
11 building blocks were injected into the infarcted heart, endog- 11
12 enous factor XIIIa (FXIIIa) could activate peptide K (Pep-K) and 12
13 peptide Q (Pep-Q) in μ Gel to induce surface binding between 13
14 μ Gel beads and form contiguous porous drugMAP scaffolds in 14
15 situ. By co-loading hydrophobic drugs of F and R, the injectable 15
16 drugMAP could endow pleiotropic benefits for heart repair by 16
17 providing mechanical support, promoting cell migration, and 17
18 neovascularization, while suppressing fibrosis and immune 18
19 responses. 19

2. Results and Discussion 22

2.1. Development of drugMAP Building Blocks 24

26 The microfluidic device for drugMAP gel generation was 26
27 designed and fabricated with soft lithography (**Figure 2A,B**). To 27
28 achieve sustained drug release from drugMAP gel, biodegrad- 28
29 able poly(lactic-co-glycolic acid) (PLGA) based polymers were 29
30 used to make drug/NPs by an emulsification solvent evapora- 30
31 tion technique, and mixed with the pregel solutions prior to 31
32 μ Gels formation. PLGA is a biodegradable polymer being used 32
33 in many FDA-approved products, and PLGA-based particles 33
34 have been widely employed for drug delivery because of their 34
35 biocompatibility and controllable biodegradation.^[30] However, 35
36 the hydrophobic PLGA NPs aggregated and precipitated quickly 36
37 in the aqueous pregel solution, leading to failure in the produc- 37
38 tion of NPs- μ Gels in a microfluidic device, because of blockage 38
39 or leakage of the microfluidic channels, and unstable processing 39
40 which caused the generation of heterogenous low-quality μ Gels 40
41 (**Figure S1**, Supporting Information). Thus, we employed two 41
42 strategies to suspend the PLGA NPs and delay particle aggrega- 42
43 tion in the pregel solution through improving NP surface 43
44 hydrophilicity and increasing the viscosity of the pregel solution 44
45 (**Figure S1**, Supporting Information). The mean hydrodynamic 45
46 diameter of NPs was \approx 400 nm with a polydispersity index of 46
47 0.23 as measured by dynamic light scattering (DLS). We first 47
48 adjusted the NP surface hydrophilicity in the aqueous pregel 48
49 solutions by using different PLGA-PEG copolymers, including 49
50 PLGA 35k, PLGA55k-*b*-PEG5k, and PLGA25k-*b*-PEG5k. We 50
51 found that particle suspension was enhanced with the increase 51
52 of PEG length, and PLGA55k-*b*-PEG5k NPs resulted in a stable 52
53 preparation of NPs- μ Gel. However, a further increase of hydro- 53
54 philicity might lead to a lower encapsulation capacity of hydro- 54
55 phobic drugs and cause a burst drug release.^[31] Thus, another 55
56 strategy was implemented in addition to the adjustment of 56
57 the particle hydrophilicity. Here, through the addition of hya- 57
58 luronic acid (HA) to the pregel solution, the solution viscosity 58
59 was increased, resulting in a reduction of NPs aggregation. 59

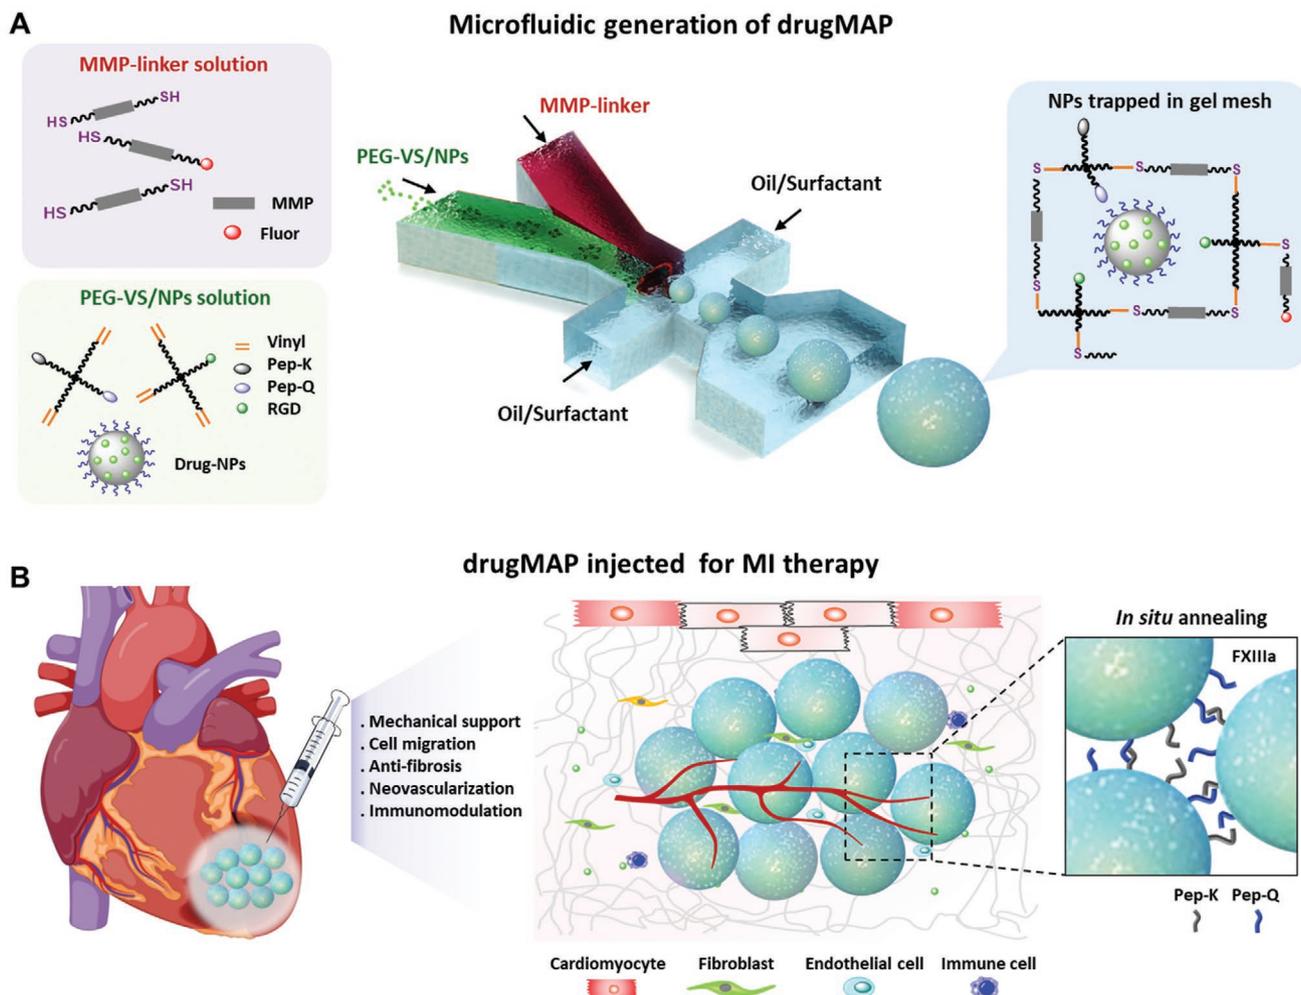

Figure 1. Scheme illustrating the microfluidic generation of drug-releasing MAP (drugMAP) scaffolds for MI therapy. A) Microfluidic generation of drugMAP building blocks by encapsulating drug/NPs into μ Gel beads to generate drug/NPs- μ Gel beads in a microfluidic device. The hydrogels are formed by crosslinking pregel solutions via thiol-ene reactions to encapsulate NPs in the gel mesh. B) Injection of cardiac drugMAP scaffolds for MI therapy. Via delivery of specific drugs, the cardiac drugMAP scaffolds endow pleiotropic benefits for heart repair.

After optimization, we found that the NPs made by PLGA35k/PLGA55k-PEG5k (1:1 weight ratio) and the addition of 0.25% v/v HA in pregel solution achieved a stable preparation of NPs- μ Gel beads with uniform size, controlled NPs loading, and uniform NPs distribution (Figure 2C–E). To monitor and visualize the mixing process of the two aqueous phases and the particle distribution in the μ Gels beads, NPs were labeled with coumarin-6 (green) and the pregel solution was conjugated with AF546-maleimide (red) (Figure 2F). The fluorescent images showed that NPs were uniformly encapsulated in the μ Gel beads (Figure 2I; Videos S1 and S2, Supporting Information). Thus, PLGA35k/PLGA55k-PEG5k NPs were used as the drug loading material for all the subsequent studies.

2.2. Characterization of drugMAP Building Blocks and Scaffolds

A major advantage of the microfluidic-emulsion technique is the production of highly monodisperse hydrogel microparticles of

well-defined size. We were able to produce NPs- μ Gel beads with diameters ranging from 45 to 120 μ m by tuning the flow rate of aqueous solutions (Figure 3A). Some minor differences in μ Gel bead formation were observed for beads containing NPs. In particular, at an aqueous flow rate of 8 μ L min^{-1} , NPs- μ Gel beads in the oil phase were larger than μ Gel beads, potentially because the addition of HA and NPs increased the viscosity of aqueous solution and affected the droplet breakup. However, NPs encapsulation slightly decreased the gel swelling ratio in buffer solution, resulting in the final diameter of NPs- μ Gel beads still being similar to μ Gel beads (≈ 100 μ m) (Figure 3B).

To adjust the drug delivery capacity of drugMAP, we prepared gel droplets loaded with different amounts of NPs from 0% to 100% (weight of NPs/weight of dry pregel components) (Figure 3C). After gelling and purification, the particle loading efficiency was higher than 90% for all tested NPs- μ Gel beads (Figure 3D), and the final NP concentration in the gels was highly correlated with the initial loading amount (Figure 3E). The NPs that were not encapsulated in the μ Gels might be lost

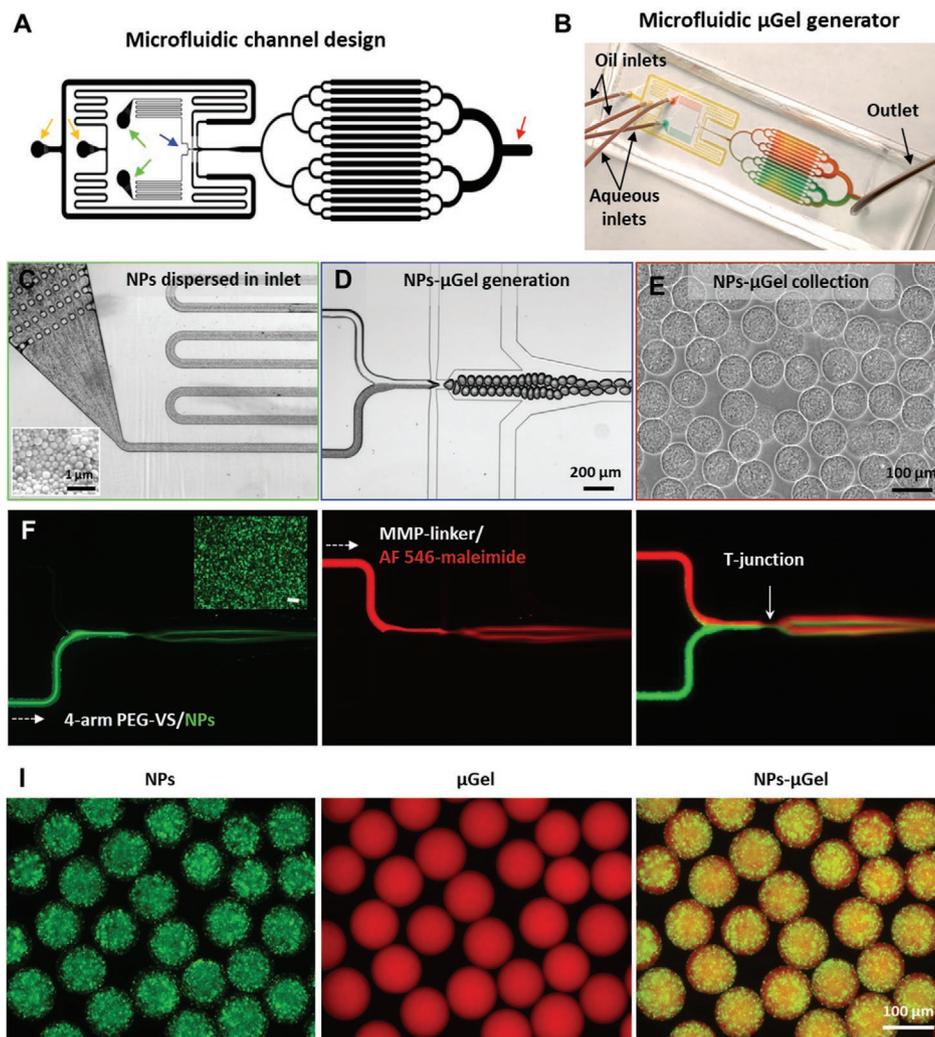

Figure 2. Preparation of drugMAP building blocks. A) Microfluidic channel design for μ Gel generator. The yellow arrows denote oil inlets. The green arrows denote aqueous inlets. The blue arrow denotes droplet generation region, and the red arrow denotes droplet collection region. B) Photograph of the microfluidic device of μ Gel generator, channels are highlighted with colored dye solutions. C) PEG-VS pregel solution with dispersed nanoparticles (NPs) flows stably through the inlet filters. Insert image in the lower-left corner is a representative SEM image of PLGA-based NPs. D) Homogeneous droplets containing pregel solution and crosslinker formed at a flow focusing junction of the microfluidic channel. E) NPs- μ Gel beads with a uniform NP distribution collected at the outlet region. F) Fluorescence images of droplets generated with fluorescently labeled aqueous solutions, one aqueous channel with coumarin-6 (green) labeled NPs with 4-arm PEG-VS pregel solution and another aqueous channel with AF 546-maleimide (red) with MMP-sensitive crosslinker solution. G) Representative fluorescent images of NPs- μ Gel beads made under optimized processing conditions, with NPs distributed uniformly in μ Gel.

in the device during gel fabrication or released during gel purification. Similar to the MAP scaffolds, the drugMAP scaffolds generated from 100 μ m NPs- μ Gel beads maintained an interconnected porous structure after annealing (Figure 3F) with a median pore diameter \approx 20 μ m and \approx 15% average void fraction (Figure 3G). With pores of these dimensions, cells can easily infiltrate and traverse the microporous scaffold even before MAPgel degradation. In addition, the pore diameters could be adjusted by tuning the building-block sizes.^[15a] The loading of NPs did not affect the ability of NPs- μ Gel beads to anneal to form contiguous microporous drugMAP scaffolds. In vitro, the building blocks were annealed via activated FXIIIa, in which a noncanonical amide covalent bond formed between the ϵ -amine

of lysine in peptide-K and the γ -carboxamide of glutamine in peptide-Q on the microbeads.^[15a,32] When the beads were injected in vivo, the endogenous thrombin and FXIIIa could induce the crosslinking of μ Gels to form MAP scaffold in the infarcted heart.^[33] Mechanical properties are critical biophysical cues in MI therapy.^[34] Therefore, the influence of nanoparticle loading on the mechanical stiffness of MAP gel was investigated. The results demonstrated that the addition of NPs in gels had a negligible effect on the hydrogel stiffness, yielding a storage modulus of \approx 600 Pa (Figure 3H). The stiffness is in the same order as the stiffness of other soft hydrogels, which have shown improved therapeutic outcomes in post-MI therapy.^[35] In particular, the porous MAP gel could provide a microporous

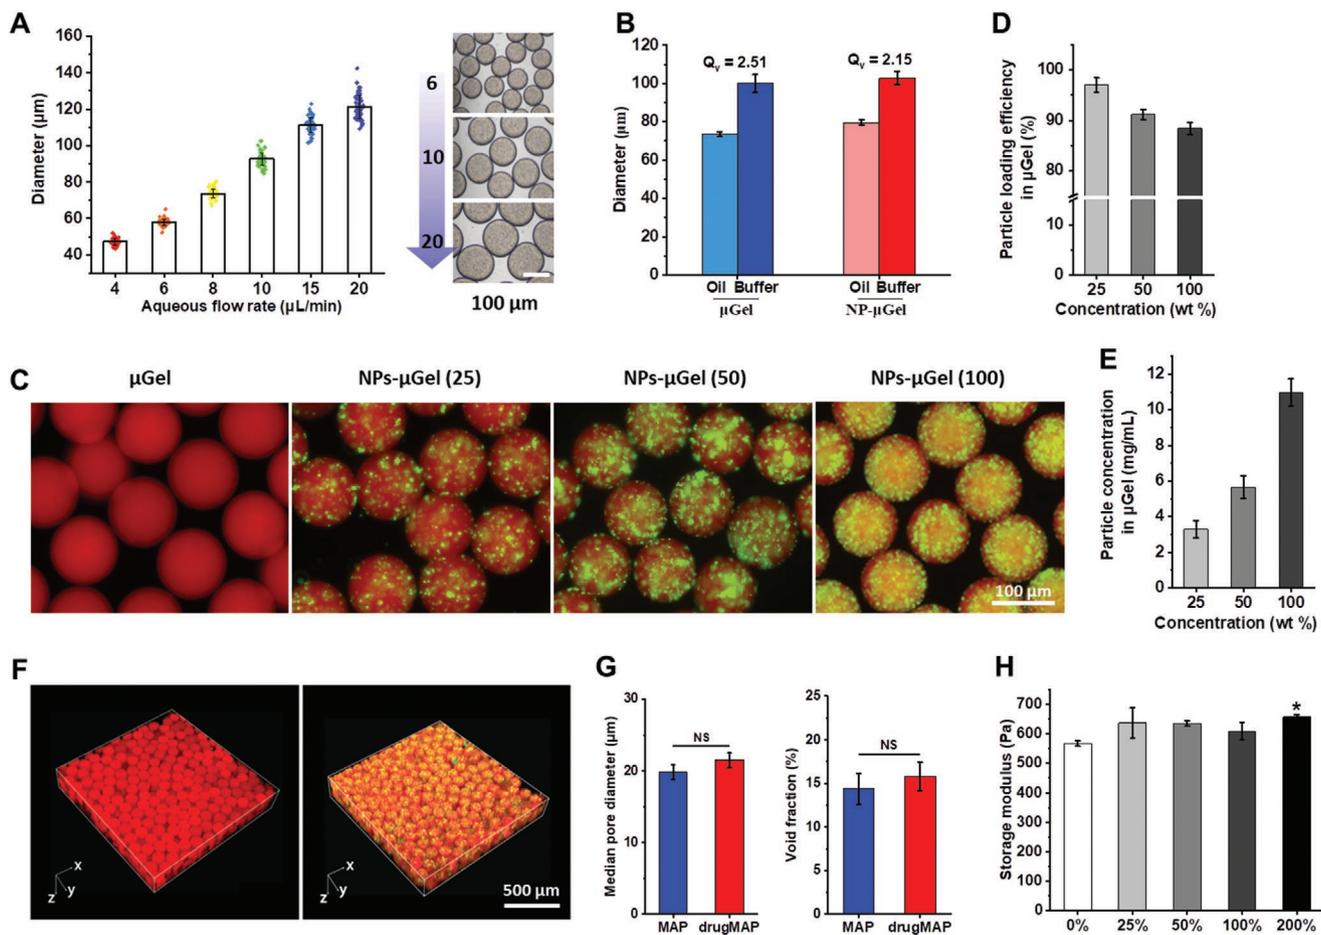

Figure 3. Characterization of drugMAP building blocks and annealed scaffolds. A) Generation of NPs- μ Gel beads with highly defined sizes by altering the aqueous flow rate. Data are shown as mean \pm SD. * $p < 0.05$, NS represents no significant difference.

structure for fast cell infiltration and mechanical support immediately after injection, and the mechanical properties of drugMAP could be easily adjusted to achieve stiffness matching between the scaffold and native tissue via modulating the stiffness of individual μ Gel beads, annealing chemistry, crosslinking degree, and bead-packing density.

The degradation of biomaterials enables in situ tissue regeneration with cell infiltration and ECM formation. The MAP gel mesh was crosslinked with MMP-sensitive peptide, making it degradable by MMP enzyme.^[36] MMPs are highly relevant to cardiac remodeling after MI as the MMP9 level is elevated in plasma and left ventricle after MI in animals and humans.^[37] To check the MAP gel degradation in enzyme solution and address whether MAP gel degradation affected the drug release profile, we loaded Coumarin-6 into drugMAP beads as a hydrophobic fluorescent model drug and characterized the degradation of pelleted NPs- μ Gel beads in the presence of MMP enzyme (collagenase II) in vitro (Figure S2A, Supporting Information). We found that the drugMAP beads degraded faster with the increase

of collagenase concentration. However, the release of coumarin-6 in NPs was not affected by changing the concentrations of collagenase. Fluorescence imaging of NPs- μ Gel beads showed a direct correlation between the collagenase concentration and the extent of degradation (represented by diminishing AF546 signal intensity) as well as particle deformability (evidenced by elongation and swelling of the particles) (Figure S2B, Supporting Information). Furthermore, we found that NPs also increased in size during degradation and remained trapped inside μ Gels. There might be two possible reasons for the particle trapping in drugMAP mesh during degradation. First, the ester bonds of polyester could be hydrolyzed to form hydrophilic carboxyl and hydroxyl groups, so the hydrophilicity of the particles would increase gradually to promote water absorption, thus forming larger swollen particles or clusters. Second, the carboxyl groups of polyester fragments could interact with the amine groups of gel components electrostatically. Overall, these in vitro data suggested that the drug release profile from the drugMAP remained relatively independent of gel degradation.

2.3. In Vitro Evaluation of Drugs and drugMAP

Previous studies have reported that F and R have specific effects on preventing cardiac dysfunction, respectively.^[27,38] However, their effects on various cell types in cardiac tissues have not been systematically evaluated, and it is not clear whether the combination of F and R has additive or synergistic effects. In the initial drug evaluation, we found that both F and R or FR combination could maintain cardiomyocyte viability at 80% after 5 days in vitro culture, which was significantly higher than 25% for control cells (Figure S3, Supporting Information). In addition, both F and R significantly enhanced the proliferation of neonatal cardiomyocytes, yielding three and six times as many cells as the control, respectively (Figure S4, Supporting Information). For cardiac fibroblasts (Figure S5A, Supporting Information), F showed dose effects to enhance fibroblast proliferation, in contrast, R showed the opposite inhibitory effects. Nevertheless, the inhibition of fibroblast proliferation can be maintained when both drugs used together. We also found that each F or R, or their combination could prevent myodifferentiation of cardiac fibroblasts (Figure S5B, Supporting Information). Furthermore, for endothelial cell (EC) proliferation and tubule network formation (Figure S6, Supporting Information), both F and R showed dose-dependent effects to enhance EC proliferation, and their optimal concentration was the same (20 μ M). Notably, EC proliferation was significantly enhanced with the combination of the two drugs. EC network formation was increased with F or FR treatment, while not with R alone. Altogether, the collected effects of both drugs on cardiac cells were summarized in **Figure 4A**. Since F and R had additive and complementary benefits in promoting cardiomyocyte survival, inhibiting fibroblast myodifferentiation and enhancing EC proliferation and tubule formation, both hydrophobic agents were loaded into PLGA-based NPs (FR/NPs), which were further encapsulated into μ Gel beads to generate FR/drugMAP building blocks.

The drug release profiles from FR/drugMAP demonstrated that both hydrophobic chemicals were gradually released throughout 2 weeks (Figure 4B). The in vitro biological evaluations were further performed for the drug-releasing platforms (Figure 4C–F). Similar to FR added directly to the medium, FR/NPs and FR/drugMAP yielded the combined beneficial effects and significantly enhanced cardiomyocyte survival compared to control (FR/NPs: 65%, FR/drugMAP: 75% versus blank: 25% at day 5) (Figure 4C,D). In addition, both α -smooth muscle actin (α -SMA) and F-actin were strongly expressed in the blank control (Figure 4E,F), and there were no differences between the blank control and the supernatants from the unloaded NPs or blank μ Gels (Figure S5, Supporting Information). However, same as adding drugs (F and R) in the medium, both FR/NPs and FR/drugMAP diminished fibroblast myodifferentiation with significantly lower α -SMA expression. In parallel, there was a decrease of F-actin in response to released F and R, suggesting that the formation of actin stress fibers was blunted in parallel with the decrease in α -SMA expression, consistent with a previous finding.^[38] Moreover, both FR/NPs and FR/drugMAP obviously enhanced EC vascular network formation (Figure 4G), and exhibited significant higher number of junctions, tubes, and meshes versus the blank control (Figure 4H).

Taken together, these in vitro results demonstrated the beneficial effects of FR/drugMAP on regulating cardiac remodeling cells, including enhancing cardiomyocyte survival, inhibiting fibroblast myodifferentiation and promoting EC proliferation and tubule formation. Beyond the controlled drug release, we found that the cellular uptake of NPs embedded in μ Gel beads were significantly reduced, compared to free NPs (Figure S7, Supporting Information), which could decrease the cytotoxicity and inflammatory response.^[39]

2.4. Cardiac Function Improvement with drugMAP Injection

To investigate the potency for cardiac repair with drugMAP, rat MI models were created by ischemia-reperfusion injury through the ligation of the left anterior descending artery. As previous studies suggested that the best therapeutic outcomes of hydrogel-based approaches were found 2–3 days after MI,^[40] we performed injections 2 days after infarction of four randomized groups with the treatments of PBS ($n = 9$), FR/NPs ($n = 6$), MAP gel ($n = 9$), and FR/drugMAP gel ($n = 9$), respectively.

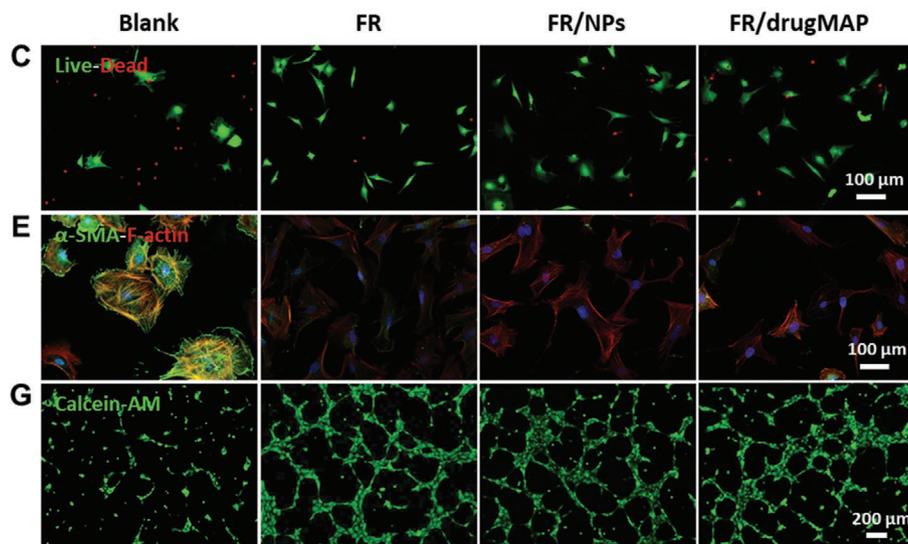

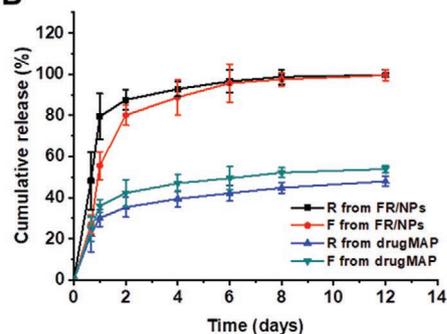

Solutions were successfully injected into the infarcted zone by ultrasound-guided transthoracic injection (total 100 μ L with two sites of 50 μ L injections). The commonly used natural and synthetic hydrogels usually undergo a solution-to-gel transition upon stimulus exposure, while it is relatively difficult to control and balance the ideal solution-to-gel transition time.^[41] Inappropriate gelation speed may lead to many adverse effects. Slow gelation (from minutes to hours) could increase tissue necrosis or the loss of materials and therapeutic molecules. On the other hand, rapid gelation (from seconds to minutes) leads to quick needle blockage, handling inconveniences and limited tissue integration. Unlike commonly applied bulk hydrogels, the MAP gel building blocks are flowable and can be easily injected into highly motile cardiac tissue and stay at the injection site without gel dislodgment, which might avoid the handling issues and risks of rapid or slow gelation.

The MI therapeutic outcomes of all groups were evaluated at 5 weeks post-treatment by histology and echocardiography analysis. Masson's trichrome staining showed the gross heart morphology and revealed less MI region, fibrosis, LV dilation, and wall thinning in hearts treated with FR/NPs- or MAP gel-only groups compared with PBS group, with further improvement for hearts treated with integrated FR/drugMAP (**Figure 5A**; Figure S8, Supporting Information), resulting in the smallest infarct size (FR/drugMAP: $15.4 \pm 3.9\%$ vs PBS: $35 \pm 6.8\%$; FR/NPs: $23.1 \pm 5.1\%$; MAP: $24.2 \pm 4.7\%$; Figure 5B) and the thickest minimum LV wall (FR/drugMAP: 1.85 ± 0.14 mm vs PBS: 1.11 ± 0.21 mm; FR/NPs: 1.45 ± 0.17 mm; MAP: 1.6 ± 0.13 mm; Figure 5C). In addition, the reduced cardiac remodeling of FR/NPs, MAP gel, and FR/drugMAP-treated groups was further demonstrated by the reduction in left ventricle end-diastolic volume (LVEDV) and end-systolic volume (LVESV), respectively, compared with PBS controls (Figure 5D,E). The ventricular ejection fractions (LVEF) at day 2 baseline were similar between all groups, indicating a similar degree of initial MI injury (Figure 5F). However, after 5 weeks, the LVEF of PBS-treated group distinctly declined, while LVEF was well preserved in the FR/NPs, MAP gel, and FR/drugMAP-

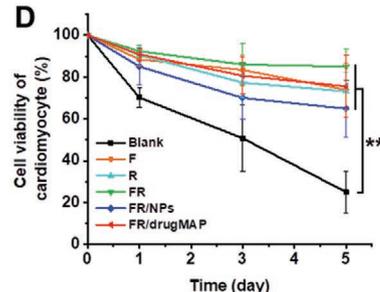

A Summarized drug effects to cardiac remodeling cells

D) LVEDV and E) LVESV of infarcted hearts measured by echocardiography at 5 weeks. E) LV ejection fraction (EF) of infarcted hearts at day 2 (baseline) and week 5 after treatment. G) Change in LVEF in comparison to baseline (Δ LVEF). Data are shown as mean \pm SD. PBS ($n = 9$), FR/NPs ($n = 6$), MAP ($n = 9$) and FR/drugMAP gel ($n = 9$). * $p < 0.05$ and ** $p < 0.01$ indicate significant difference in comparison to the PBS control group. # $p < 0.05$ and ## $p < 0.01$ in (F) indicate comparisons of 5 week treated group to the corresponding baseline. NS represents no significant difference.

attenuated by the treatment with FR/NPs or MAP gel alone, indicating the respective benefits of the drugs (F and R)^[27,38] and hydrogel-based mechanical support^[5,9] in ameliorating

post-MI remodeling and rescuing cardiac dysfunction. Compared to treatment alone, the integrated FR/drugMAP showed the best therapeutic outcomes.

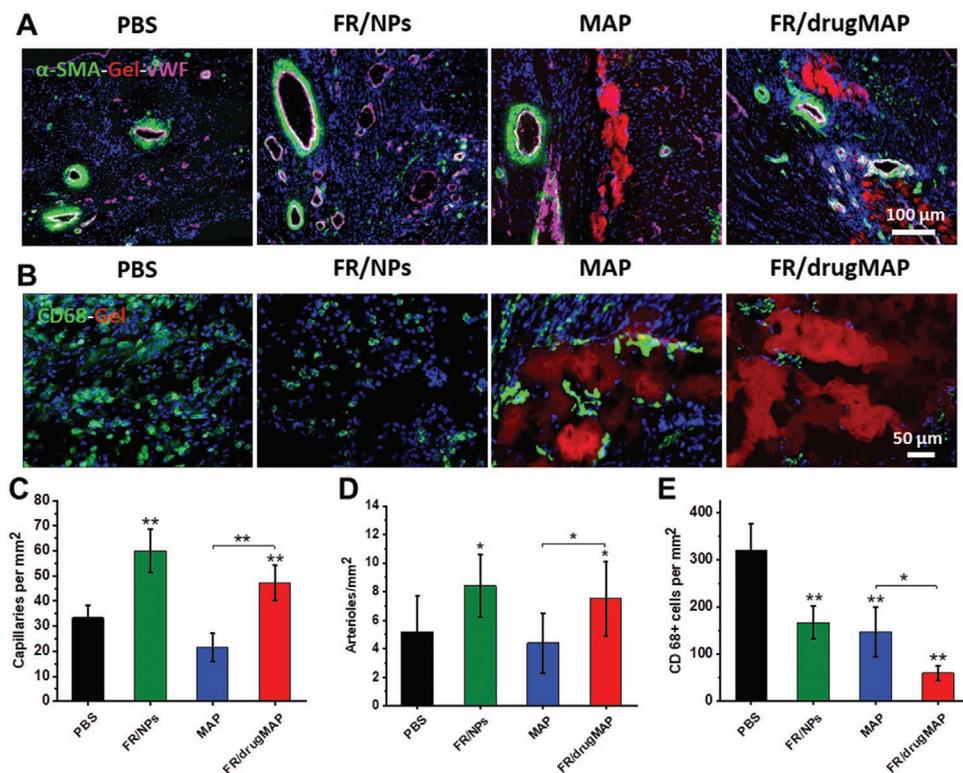

Figure 6. DrugMAP promotes angiogenesis and reduces inflammatory response in MI therapy. A) Representative images of angiogenesis staining with α -SMA (green) and vWF (magenta) in the central infarct LV zone of hearts treated with PBS, FR/NPs, MAP, and FR/drugMAP gel at 5 weeks. Microgel beads were labeled by AF546 dye (red) for material tracking. B) Representative images of macrophage staining with CD68 (green). Quantification of C) capillary density (vWF+ vessels), D) arteriolar density (α -SMA+ vessels) and E) macrophage density in the central infarct LV zone of hearts treated with PBS ($n = 9$), FR/NPs ($n = 6$), MAP ($n = 9$), and FR/drugMAP ($n = 9$) at 5 weeks. Data are shown as mean \pm SD. * $p < 0.05$ and ** $p < 0.01$ indicate significant difference in comparison to PBS control group.

To reveal the underlying mechanisms for the functional effects of drugMAP, we further performed immunostaining analysis and assessed angiogenesis and immune response in the infarcted hearts (Figure 6). Infarcted hearts were stained with von Willebrand factor (vWF, for ECs) and α -SMA (for smooth muscle cells) (Figure 6A; Figure S9, Supporting Information), and the results showed that the numbers of both capillaries (vWF+) and arterioles (α -SMA+) were significantly increased in FR/NP-treated and FR/drugMAP-treated groups in comparison to PBS and MAP-treated groups (Figure 6C,D). Notably, the FR/drugMAP-treated hearts exhibited prominent angiogenesis, while there was less angiogenesis treated with MAP gel alone, suggesting that the drugs further promote neovascularization. Additionally, in contrast to PBS-treated hearts, other three treatments showed less CD68+ macrophage infiltration in the infarcted hearts, especially for the FR/drugMAP-treated group (Figure 6B,E; Figure S10, Supporting Information), demonstrating that both drug and MAP gel could reduce the inflammatory responses in MI hearts, and their combination and integration could further enhance the efficiency. Together, these in vivo results suggest that the integrated drugMAP could enhance the MI therapeutic effects through the promotion of neovascularization and the inhibition of inflammatory response.

To date, numerous injectable hydrogels have been investigated for cardiac repair and regeneration. However, rapid host

tissue integration and spatiotemporal control of biologics presentation are challenges for most natural and synthetic bulk hydrogels, which can compromise the efficacy of the hydrogel-based therapy for cardiac repair. In recent years, very few granular hydrogels have been exploited in tissue repair.^[15a,16,42] By annealing the μ Gel building blocks to form porous scaffolds, the granular hydrogel permits several noteworthy features. First, the small size of μ Gel enables minimally invasive injection. Second, the modular building makes it flexible to engineer multiscale physical properties by varying polymer composition, μ Gel shape, size and stiffness, and interparticle friction. Third, granular hydrogels possess porosity and diffusivity and can be tuned to support cell proliferation and migration. For example, the injection of granular porous hyaluronic acid hydrogels into myocardial tissues demonstrated the degradation behavior and cell invasion after 3 weeks.^[43] However, this study did not evaluate the MI therapeutic outcomes by histology and echocardiography analysis.

Injectable hydrogels are promising for localized drug and cell delivery in many biomedical applications. Current granular hydrogel systems have been used for the sustained delivery of hydrophilic biologics (cells and drugs). For example, heparin has been incorporated into microparticles to sustain the delivery of growth factors through electrostatic associations.^[44] Similarly, protein activators or inhibitors such as antibodies can also be delivered, while they are more expensive and may lose activity through

1 proteolytic enzymatic digestion and degradation over time. In
2 contrast, small molecules are generally more stable, cheaper,
3 and easier to be loaded into a drug delivery system. However, it
4 is still challenging to pack hydrophobic drugs into microfluidic-
5 generated granular hydrogel systems. Delivery of hydrophobic
6 drugs or cargos can be controlled by loading the drugs into
7 hydrophobic carriers (such as NPs). However, these hydrophobic
8 particles can aggregate into clusters and precipitate quickly in the
9 hydrophilic pregel solution, resulting in the blockage of micro-
10 fluidic channels and unstable drug loading, as shown in this
11 study. Here we achieved the uniform encapsulation hydrophobic
12 drug-loaded NPs within microfluidic-generated hydrophilic μ Gel
13 beads by modulating NP surface hydrophilicity and the viscosity
14 of the pregel solution for controlled hydrophobic drug delivery.

15 In this study, F and R were evaluated and loaded into the
16 drugMAP for MI therapy. Both hydrophobic drugs can be sus-
17 tained release in two weeks in vitro. There was a partial release
18 of both drugs during the production phase of drugMAP, due to
19 the burst release occurring when the NPs were suspended in an
20 aqueous pregel solution or embedded in MAP gel. Depending
21 on the therapeutic purpose, the drug release period from NPs
22 can be tailored from hours to months, by tuning the polymer
23 composition, molecular weight, and the content of the hydro-
24 philic block.^[31,45] Besides the intrinsic release profile from drug-
25 loaded NPs, the amount of NPs encapsulated in each μ Gel and
26 the volume of μ Gels are also critical parameters to determine the
27 overall drug release profile and pharmacologic effects. Further-
28 more, we have systematically analyzed the MI therapeutic out-
29 comes of drugMAP systems by histology, echocardiography and
30 immunostaining. We found that the integrated FR/drugMAP
31 could significantly ameliorate cardiac remodeling and dysfunc-
32 tion, in comparison to FR/NPs only and MAP-only groups, by
33 inhibiting fibrosis and inflammatory response, and promoting
34 cell migration and neovascularization. It is worth noting that
35 the drugMAP gel has shown partial degradation in vivo after 5
36 weeks. A longer study is needed to determine the potential long-
37 term benefits on cardiac repair, and large animal studies need to
38 be performed before advancing into clinical studies.

3. Conclusions

43 In summary, we first developed an annealing drug-releasing
44 drugMAP hydrogel, through overcoming challenges in inte-
45 grating hydrophobic NPs within microfluidic-generated
46 hydrophilic μ Gel beads. DrugMAP was loaded with
47 hydrophobic drugs (F and R), and injected into ischemic heart,
48 which promoted cardiac repair by offering multifunctional ben-
49 efits, including fast cell infiltration, mechanical support, and
50 synergistic pharmacological effects. Our findings suggest that
51 drugMAP has a great potential for MI therapy and broad bio-
52 medical applications in soft tissue repairs and disease therapies.

4. Experimental Section

57 *Microfluidic Device Fabrication:* Droplet generating microfluidic
58 devices were fabricated by soft lithography as previously described.^[15a]
59 Briefly, master molds were fabricated on silicon wafers (University

1 wafer) using two-layer photolithography with KMPR 1050 photoresist
2 (Microchem Corp). The height for the droplet formation channel was
3 50 μ m, and the height for the collection channel was 150 μ m. Devices
4 were molded from the masters using poly(dimethyl)siloxane (PDMS)
5 (Sylgard 184 kit, Dow Corning). The base and crosslinker were mixed
6 at a 10:1 mass ratio, poured over the mold and degassed before curing
7 overnight at 65 °C. Channels were sealed by treating the PDMS mold
8 and a glass microscope slide (VWR) with oxygen plasma (Plasma
9 Cleaner, Harrick Plasma) at 500 mTorr and 80 W for 30 s. Thereafter,
10 the channels were functionalized by injecting 100 μ L of Aquapel
11 (88625-47100, Aquapel) and reacting for 30 s until washed by Novoc
12 7500 (9802122937, 3M). The channels were dried by air suction and kept
13 in the oven at 65 °C until used.

14 *Preparation and Characterization of Drug-Loaded NPs:* An emulsification
15 solvent evaporation technique was applied to prepare NPs.^[46] Briefly,
16 different PLGA based polymers, including PLGA ($M_w = 35$ kDa, acid-
17 terminated, cat# 26270, Polysciences), PLGA55k-b-PEG5k (PLGA
18 average $M_n = 55$ kDa, PEG average $M_n = 5$ kDa, cat# 764752, Sigma),
19 PLGA25k-b-PEG5k (PLGA average $M_n = 25$ kDa, PEG average
20 $M_n = 5$ kDa, cat# 764 752, Sigma), and mixed PLGA35k/PLGA55k-b-
21 PEG5k (50/50 wt/wt) were dissolved in dichloromethane to make 10%
22 w/v solutions. The resulting solution (1 mL) was added to stirred 3 mL
23 1% (w/v) poly(vinyl alcohol) (PVA, $M_w = 25$ kDa, 88% hydrolyzed, cat#
24 15132, Polysciences) solution using a vortex mixer at 2000 rpm for 2 min,
25 and the emulsified polymer solution was immediately sonicated with
26 a 20% amplitude (Sonic Dismembrator 500, Thermo Fisher Scientific)
27 in six 10 s bursts. The test tube was immersed in ice water during
28 sonication. After sonication, the emulsion was added dropwise into
29 30 mL 1% (w/v) PVA solution and stirred for 3 h at room temperature
30 to remove the residual organic solvent. NPs were collected and
31 washed three times with distilled water by centrifugation at 10 000 $\times g$
32 for 5 min at 4 °C, and the NPs were stored at -80 °C refrigerator. Particle
33 diameter was measured by dynamic light scattering (DLS), and the
34 surface morphology was observed by SEM with gold electro spray.

35 To prepare the fluorescence-labeled NPs, 0.02% (w/v) coumarin-6
36 (green fluorescence, Sigma) was added and dissolved in the polymer
37 solution for NPs fabrication. In addition, forskolin (cat# 11018, Cayman
38 Chemical) and Repox (cat# 14794, Cayman Chemical) were selected
39 and loaded into NPs to generate FR/NPs. The aforementioned protocol
40 was used, but 5% (wt/wt) of hydrophobic drugs with the same molar
41 ratio of F and R were added and dissolved in the polymer solution of
42 PLGA35k/PLGA55k-b-PEG5k (50/50 wt/wt).

43 *Preparation of drugMAP Building Blocks:* The MMP sensitive
44 PEG-based microgel (μ Gel) beads were prepared by a customized
45 microfluidic device with two separate pregel aqueous solutions,
46 as previously described.^[15a] Aqueous solution 1: 10% (w/v) 4-arm
47 PEG vinyl sulfone ($M_w = 20$ kDa, JenKem Technology USA Inc.) in
48 300 $\times 10^{-3}$ M triethylamine (Sigma), pH 8.25, prereacted with 250 $\times 10^{-6}$ M
49 K-peptide (Ac-FKGGERC-NH₂, Genscript), 250 $\times 10^{-6}$ M Q-peptide
50 (Ac-NQEQVSPGGERC-NH₂, Genscript), and 500 $\times 10^{-6}$ M RGD
51 peptide (Ac-RGDSPGERC-NH₂, Genscript). Aqueous solution 2: 8 \times
52 10⁻³ M dicysteine modified metalloprotease-sensitive peptide crosslinker
53 (MMP-sensitive crosslinker, Ac-GCRDGPQGIWQDRCC-NH₂,
54 Genscript), prereacted with 10 $\times 10^{-6}$ M Alexa-fluor 568-maleimide (Life
55 Technologies).

56 Both aqueous solutions were injected at the defined flow rates in
57 a 1:1 volume mixture. Meanwhile, Novoc 7500 Engineered Fluid (cat#
58 7100025016, 3M) with 0.1% Pico-Surf (SF-000149, Sphere Fluidics) acting
59 as a surfactant was used as the continuous oil phase, with the flow rate
60 at 150 μ L mL⁻¹. μ Gel beads were collected into a Corning centrifuge tube
61 and cured at 37 °C for two hours. Thereafter, the cured μ Gel beads were
62 extracted and purified from the oil phase with a mixed solution of HEPES
63 buffer (100 $\times 10^{-3}$ M HEPES, 40 $\times 10^{-3}$ M NaCl, pH 7.4) and hexane in a
64 1:1 volume, and centrifuged at 3000 rpm for 5 min at 4 °C. The μ Gel
65 pellets were further washed in HEPES buffer with 0.01% w/v Pluronic
66 F-127 (Sigma) for five times to move the resident oil components. The
67 μ Gel aqueous solution was further allowed to swell and equilibrate with
68 HEPES buffer at 4 °C.

To make NPs encapsulated microgel (NPs- μ Gel), different amounts of NPs (0%, 25%, 50%, 100% weight percentage of NPs to the weight of dry pregel components) was dispersed in aqueous solution 1. To enhance the uniform distribution of NPs in the μ Gel and stable droplet preparation, 0.25% (w/v) hyaluronic acid (HA700K, Lifecore Biomedical, LLC) was added in the dispersed particle solution.

For in vitro cell culture and in vivo evaluation, all μ Gel beads (pure μ Gel, NPs- μ Gel, FR/drugMAP) were prepared with sterilized devices (PDMS device, connecting tubes) and sterile filtered pregel components by a 0.2 μ m polyethersulfone membrane. All procedures were performed in a biosafety cabinet.

Size and Swelling Ratio: To determine the operational regime of droplet generation, at least five images of droplets in the channel were taken using a high-speed camera (Phantom) at each flow rate condition. The size distribution was analyzed by a custom-developed MATLAB code. The size of swollen μ Gel droplets in buffer solution was also measured in the same manner, and the volume swelling ratio was calculated by the following equation

$$Q_v = \frac{d_{aq}^3}{d_{oil}^3} \quad (1)$$

where Q_v is the volume swelling ratio of a single droplet, d_{aq} is the diameter of droplets in the aqueous phase (HEPES buffer), and d_{oil} is the diameter in the oil phase (Novex 7500).

NP Loading Concentration and Efficiency in μ Gel: The NP loading concentration in μ Gel was quantified by measuring fluorescent intensity of coumarin-labeled NPs. Briefly, the concentrated coumarin-labeled NPs- μ Gel beads were diluted with HEPES buffer, and 100 μ L solution was transferred to a 96-well plate to measure the fluorescent intensity (excitation: 485 nm, emission: 528 nm) by using a plate-reader. Meanwhile, the coumarin-labeled NPs were diluted in HEPES buffer (0 to 8 mg mL⁻¹, 10 serial dilution points) to make the standard curve. The NPs loading efficiency was calculated by the following equation

$$\text{Particle loading efficiency (\%)} = 100 \times \left(\frac{\text{Particle loading concentration} \times \text{Swollen volume}}{\text{Primary loading amount}} \right) \quad (2)$$

Degradation of drugMAP Building Blocks: To study the degradation and model drug release profiles of drugMAP building blocks, NPs were labeled by coumarin-6 dye and μ Gels were labeled by AF546 dye. 100 μ L of NPs- μ Gel beads were added to the 1 mL PBS or collagenase II solutions (ranging from 1.6 mU mL⁻¹ to 1 U mL⁻¹ in PBS with calcium and magnesium) in centrifuge tubes and incubated at 37 °C with rotation at 20 rpm ($n = 4$ for each group). Three days later, hydrogel beads were centrifuged at 6000 rpm for 5 min, and 200 μ L of the supernatant was transferred to a 96-well plate for measuring the release of coumarin-6 (excitation: 485 nm, emission: 528 nm) and AF546 (excitation: 556, emission: 573 nm) using a plate reader as surrogates for model drug release and hydrogel degradation, respectively. The μ Gel beads were washed three times with PBS, and pushed through a 110 μ m \times 110 μ m square microfluidic channel and imaged with fluorescence microscopy to measure the remaining model drug and AF546 as well as the deformability and swollen shape of the μ Gel beads.

Pore Size and Void Fraction of MAP and drugMAP Scaffolds: Fully swollen and equilibrated MAP or drugMAP building blocks (20 μ L) were activated by with 5 U mL⁻¹ FXIIIa (Sigma) and 1 U mL⁻¹ thrombin (Sigma), and the mixture was pipetted into a 3 mm diameter PDMS well on a glass coverslip, and annealed in a humidified incubator at 37 °C for 1.5 h to form porous MAP or drugMAP scaffolds. Thereafter, the scaffolds were placed into HEPES buffer (pH 7.4) overnight to reach equilibrium. Samples were 3D imaged using a Leica TCS SP8 confocal microscope with 10 \times objective, spanning 1.16 mm \times 1.16 mm (in x- and y-axis) \times 200 μ m (in z-axis). The pore size was analyzed using a custom script written in MATLAB and the void fraction was calculated using ImageJ (stack function).

Rheology Properties: To determine the effects of particle loading amount on the gelation and gel rheology properties, rheological measurements were performed on bulk gel samples using a DHR-2 rheometer (TA Instruments). Briefly, different amounts of PLGA35k/PLGA55k-b-PEG5k (50/50) NPs (0%, 25%, 50%, 100%, 200% of PEG weight) were quickly vortexed with two pregel aqueous solutions (basic aqueous solution 1 and 2 in 1:1 volume). To make a disk gel sample, a 40 μ L mixed particle-containing solution was pipetted onto sterile slide glass siliconized with Sigmacote (SL2-25ML, Sigma-Aldrich), and covered with another glass slides with 1 mm spacer, followed with curing at 37 °C for 2 h. Disc gels were swollen to equilibrium in HEPES buffer overnight before rheological measurements. A frequency sweep of 0.1–10 Hz was performed by using an 8 mm Peltier Plate-Crosshatched surface (TA Instruments), and the storage modulus and loss modulus were calculated from the average of the linear range. At least, four-disc gel samples were measured for each condition.

Drug Release Assay: Briefly, 2 mg of FR/NPs or 200 μ L FR/drugMAP beads was dispersed in a 0.22 μ m filters inserted in a centrifuge tube (Corning Costar Spin-X Centrifuge Tube, Thermo Fisher Scientific) with 1 mL PBS (pH 7.4) at 37 °C, with continuous shaking. At discrete time intervals (16 h, 1, 2, 4, 6 days), 0.5 mL of the sample solution was collected from the tube and frozen for the later analysis. Aliquots of the solutions were analyzed by reversed-phase separation and detection using tandem mass spectrometry with multiple reactions monitoring with previously optimized conditions for parent ion production and fragment ion detection on a triple quadrupole mass spectrometer (Agilent 6460). Quantification was achieved with the external standards for both analytes. All experimental samples were analyzed in triplicate and all results were reported as mean \pm standard error of the mean.

Cellular Uptake of NPs: To check cellular uptake of NPs released from NPs- μ Gels, primary mice skin fibroblasts were seeded in 24-well plates at the density of 10 000 cells cm⁻² and coincubated with 0.1 mg coumarin-labeled NPs or 20 μ L NPs- μ Gel (50) beads (around the same weight of NPs) in the inserted Transwell (8 μ m pore size), and cultured in the DMEM medium supplemented with 10% fetal bovine serum (FBS) and 1% penicillin/streptomycin (P/S). Cells were incubated in a humidified atmosphere containing 5% CO₂ at 37 °C. Adhered cells were washed twice with PBS and fixed with 4% paraformaldehyde (PFA) on day 1 and day 4. The samples were stained with phalloidin F-actin and DAPI. The fluorescent images were taken by Zeiss Axio Observer Z1 inverted microscope and the fluorescent intensity was measured by Image J.

Cell Isolation: Primary neonatal rat cardiomyocytes and fibroblasts were isolated from the hearts of 1–2 day old Sprague-Dawley rat pups as described previously with minor modifications.^[47] Briefly, the cardiac tissue was minced and digested with 80 units mL⁻¹ collagenase II (Worthington) and 0.8 mg mL⁻¹ pancreatin (Sigma) at 37 °C in a water bath. Neonatal calf serum (NCS) was applied to inactivate enzymatic activity in the digested cell mixture. The cell solution was filtered through 100 μ m mesh and centrifuged at 2200 rpm for 3 min. The cell pellets were suspended in 1 mL NCS and further separated by Percoll density gradient centrifugation. A two-layer density gradient was formed consisting of 40.5% Percoll (GE17-0891-01, Sigma) solution in the top layer and 58.5% Percoll solution in the bottom layer. The cell suspension was layered on top of the gradient and centrifuged at 3000 rpm at room temperature for 30 min. Fibroblasts equilibrated and collected from the top of the transparent Percoll solution. Cardiomyocytes could subsequently be removed from the newly formed layer between the Percoll solutions and harvested separately. Both cells were washed with warm DMEM medium containing 10% FBS and 1% P/S and used immediately.

Cell Culture and Evaluation of Drug Effects In Vitro: The drug effects on cardiomyocyte viability and proliferation were evaluated. Isolated cardiomyocytes were calculated and seeded on 0.1% gelatin-coated twenty-four well tissue culture plate with a density of 20 000 cells cm⁻², and cultured at 37 °C in a humidified, 5% CO₂ incubator overnight in DMEM/medium 199 (4/1) containing 10% FBS, 1% NEAAs, and 1% P/S. The next day, the culture medium was replaced by fresh medium containing 20 \times 10⁻⁶ m F, R or their combination. The medium was

changed every other day. Cell viability assay and proliferation assay of cardiomyocytes were performed at days 1, 3, and 5. A live/dead kit (Invitrogen) was for cell viability assay, and images were taken using inverted microscope fluorescence microscopy (Zeiss Axio Observer Z1) to determine the cell numbers and the percentage of dead cells. To analyze the proliferation of cardiomyocyte, cells were stained by the Click-iT EdU assay (Invitrogen) as the vendor-provided protocol. Briefly, cells treated with EdU concentration of 10×10^{-6} M for 24 h before fixing with 4% PFA in PBS, followed with EdU detection and immunofluorescent staining with cTnT antibody (DSHB).

The drug effects on cardiac fibroblast proliferation and myodifferentiation were evaluated. Fibroblasts were seeded on 24-well tissue culture plate with a density of 5000 cells cm^{-2} and cultured overnight in DMEM containing 10% FBS and 1% P/S. On the next day, the culture medium was replaced by the fresh medium containing F and R at the determined concentrations and combinations, and the medium was changed every other day. MTS cell proliferation assay (cat# PR-G3582, Thermo Fisher Scientific) was performed on days 1, 3, and 5 by following the protocol from the manufacturer. Meanwhile, some cells were fixed with 4% PFA for myodifferentiation assay by fluorescent staining using α -SMA antibody (Abcam) and phalloidin (for F-actin) (Thermo Fisher Scientific).

The drug effects on EC proliferation and network formation were evaluated. Human umbilical vein endothelial cells (HUVECs) were seeded on 0.1% gelatin-coated 24-well plates with a density of 5000 cells cm^{-2} and cultured overnight in DMEM containing 10% FBS and 1% P/S. On the next day, the culture medium was replaced by the fresh medium containing F and R at the determined concentrations and combinations, and the medium was changed every other day. MTS cell proliferation assay was performed on day 1, 3, and 5. In addition, the ECs network formation was examined on growth factor reduced Matrigel according to the manufacturer's instructions (cat# CB-40230C, Thermo Fisher Scientific). Briefly, 24-well plates were coated with Matrigel. ECs were digested and plated onto a layer of Matrigel at a density of 3×10^5 cells per well in M199 medium containing 1% FBS and 1% P/S, with the addition of F and R. Vascular endothelial growth factor (VEGF, 20 ng mL^{-1}) was used as a positive control. After 16 h of culture, cells were stained with calcein acetoxymethyl ester (calcein-AM) and observed with an inverted fluorescent microscope. The number of tubular structure, junctions and meshes were analyzed by Image J with the Angiogenesis Analyzer plugin ($n = 4-6$ per group).

The effects of drugs released from FR/NPs and FR/NPs- μ Gel beads were evaluated using the methods mentioned above. During cell culture, 2 mg FR/NPs or 100 μL FR/NPs- μ Gel (100) (theoretical loading weight of NPs ≈ 2 mg) was added in the inserted Transwell (0.4 μm pore size) in 24-well plates with cultured cells.

MI Model and Intramyocardial Injection of drugMAP: All animal work was conducted under protocols approved by the University of California Los Angeles (#2016-101-11) and the University of California San Francisco (#AN176681-02) and was performed in accordance with the recommendations of the American Association for Accreditation of Laboratory Animal Care. The ischemia-reperfusion MI model was established as previously described.^[40b] Briefly, the left anterior descending coronary artery of female Sprague-Dawley rats (200–250 g, 8–10 weeks) underwent ligation for 30 min, followed by reperfusion. The intramyocardial injections (50 μL , twice) of sterile PBS, FR/NPs (20 mg mL^{-1} in PBS), MAP gel and FR/drugMAP gel were performed 2 days post-MI via ultrasound-guided transthoracic injection using a 27-gauge syringe. The successful injection was confirmed by a slight local increase of ultrasound signal in the LV wall.

Echocardiographic Assessment: Echocardiography was performed at 2-day post-MI and five weeks post-injection using standard methods as previously described.^[40b,48] Transthoracic echocardiography was performed with a 15-MHz linear array transducer system (Sequoia c256, Acuson, Erlangen, Germany) on all animals anesthetized with isoflurane. The left ventricular end-diastolic volume (LVEDV), left ventricular end-systolic volume (LVESV), and ejection fraction (LVEF) were measured. All measurements were the averages of three consecutive cardiac cycles.

Cases where ejection fraction was above 45% at day 2 were excluded from echocardiographic and histological analyses because they indicated an insufficient infarct model.

Histology and Immunostaining: At 5 weeks after the injection, all rats were sacrificed for tissue harvesting. The hearts were embedded in optimal cutting temperature (OCT) compound, fresh frozen by dry ice immediately, and stored at -80 °C. All tissue blocks were cryosectioned at a thickness of 10 μm by a cryostat microtome (HM525 NX, Thermo Fisher Scientific) starting from the apex of the left ventricle, and 10 serial sections were collected for every 500 μm intervals. All slides were kept at -20 °C for later staining.

Sections were stained with Masson's trichrome staining using standard protocols and images were captured with an inverted microscope (Nikon, Eclipse Ti-S fluorescence microscope). Masson's-trichrome staining images were used to evaluate the infarct size, fibrosis area and LV wall thickness with Image J software. The infarct size or scar area (% LV) was calculated by dividing the collagen deposited area to the entire left ventricle area. LV wall thickness was calculated by averaging the minimum infarcted LV wall thickness of all samples for each group.

For immunofluorescent staining, cell samples or air-dried tissue slides were fixed with 4% PFA for 10 min at room temperature, permeabilized with 0.1% Triton X-100 for 15 min, and blocked with 10% normal goat serum for 1 h at room temperature. The cell samples and slides were incubated with primary antibodies, against α -SMA (rabbit, Abcam, ab5694, 1:300), Von Willebrand Factor (vWF, sheep, Abcam, ab11713), CD68 (mouse, Abcam, ab955, 1:300), cardiac Troponin T (cTnT, mouse, DSHB, 1:200) or Ki67 (Rabbit, Abcam, ab16667, 1:200) overnight at 4 °C. Thereafter, appropriate Alexafluor 488- or Alexafluor 546- or Alexa fluor 637-conjugated secondary antibodies (Thermo Fisher Scientific) was added and incubated for 1 h at room temperature. Thereafter, nuclei were stained with 4',6-diamidino-2-phenylindole (DAPI, 1:2500 in sterilized deionized water, Sigma) for 10 minutes in the dark. All fluorescent images were taken with Zeiss Axio Observer Z1 inverted microscope and confocal Inverted Leica TCS-SP8-SMD Confocal Microscope.

Statistical Analysis: Data are presented as means \pm standard deviations, calculated from the average of at least three biological replicates unless otherwise specified. Statistical analysis was performed using one-way analysis of variance (ANOVA), followed by post-hoc analysis with Turkey's test using Origin 8 software. p values < 0.05 were considered statistically significant.

Supporting Information

Supporting Information is available from the Wiley Online Library or from the author.

Acknowledgements

J.F., J.K., and Q.F. contributed equally to this work. The authors were supported in part by a grant from the National Institutes of Health (HL121450 to S.L.), the National Institute of Arthritis and Musculoskeletal and Skin Diseases of the NIH under the Ruth L. Kirschstein National Research Service Award (T32AR059033 to J.S.), UCLA Eli and Edythe Broad Center of Regenerative Medicine and Stem Cell Research Innovation Award (to S.L.), UCLA startup funding, by the Presidential Early Career Award for Scientists and Engineers (N00014-16-1-2997 to D.D.C.), Kwanjeong Graduate Scholarship (to J.K.), and UCLA MSTP training grant (NIH NIGMS training grant GM008042). SEM was performed at the California NanoSystems Institute (CNSI) Electron Imaging Center for NanoMachines (EICN) Shared Resource Facility at UCLA. Confocal laser scanning microscopy was performed at the California NanoSystems Institute (CNSI) Advanced Light Microscopy/Spectroscopy Shared Resource Facility at UCLA.

Conflict of Interest

The authors declare no conflict of interest.

Keywords

drug delivery, granular hydrogel, microgel, myocardial infarction, tissue engineering
